

The Data Engine, as Flowcharts

No code — just the paths a child's data takes through the app: how it's saved, kept safe, removed, and exported. Each flow has a one-line plain reading underneath.

-  where things start  the safe core  where they land  a decision point

01 One doorway for everything

No matter what the teacher does, all data passes through a single checkpoint.

In plain terms: because everything funnels through one checkpoint, we can change what's behind it — phone storage today, cloud tomorrow — without touching any of the screens you design.

02 Which storage, decided once at launch

The app figures out where it's running and chooses the right place to keep data — automatically.

In plain terms: teachers always get durable phone storage. The browser version exists only so the team can work without a phone plugged in.

03 Saving — the part that can't fail quietly

A save isn't trusted until the app re-reads it and confirms it's really there.

In plain terms: the app never *assumes* a save worked. For children's records, a result that silently vanishes is the worst outcome — so the app checks every single time and speaks up if anything's wrong.

04 What gets stored for each child

Three kinds of information, each in its own labelled drawer.

Two quiet smart touches: age is *calculated* from the date of birth, never frozen, so it's never out of date — and any photo is automatically shrunk to a small, low-detail image before storage, for privacy and size.

05 Deleting data — built in, not bolted on

Because this is children's disability data, clean removal is a proper feature with three levels.

THREE LEVELS OF REMOVAL

Remove one result — a single mistaken entry disappears

Remove a whole child — the profile *and* every session linked to them, swept away together

Wipe the device — everything cleared at once

Every delete asks "**are you sure?**" and points to "export a backup first"

In plain terms: "delete a child and all their data" is exactly the erasure ability the data-protection law expects — and it already works.

06 Getting data out — the export

A teacher can pull everything into a spreadsheet they can open in Excel or Google Sheets.

EXPORT, START TO FINISH

Gather

collect every record
across all activities

Join

attach each child's
details to their results

Build sheet

a clean spreadsheet,
safe for Indian-
language names

Share

save to Files, Drive, or
email

In plain terms: phones don't have a "download" like a browser, so the app hands the finished spreadsheet to Android's share menu — the teacher chooses where it goes. Until cloud sync is switched on, this is the way data leaves the device.

07 Where it stands today

What's working now, what's partly there, and what's designed but waiting.

Capability	Status	One-line note
Data kept safely on the phone	Working	survives restarts
Every save verified (no silent loss)	Working	checked each time
Child profiles + shrunk photos	Working	privacy by default
Delete a result / child / everything	Working	erasure built in
Export to spreadsheet	Working	via share menu
SOP narration in Hindi/Tamil/Bengali	In progress	plumbing done; audio added per activity
Testing on a physical Android phone	Next up	works on the emulator so far
Cloud storage & session video	Designed	switched on after a policy decision

The one decision that's yours, not engineering's: the app keeps everything on the device *on purpose*. Cloud sync and video storage are fully planned but deliberately **off**, because turning them on crosses a consent-and-data-sharing line that's a product and policy call — not a missing piece of work. Everything that can ship safely today already runs.
